***Abstract*—Household participation in capital markets is a crucial driver of financial inclusion and wealth creation, yet it remains disproportionately skewed across demographic lines. Using a large-scale micro-dataset from the 2025 SEBI Household Survey ($N = 109,430$), this paper empirically analyzes the determinants of securities market participation in India. We employ a weighted logistic regression framework with HC3 robust standard errors across eleven demographic, socioeconomic, and geographic predictors, revealing that education and income are the strongest drivers (odds ratios of 1.86 and 1.80, respectively; $p < 0.001$), while two predictors (Gen X life stage and West zone) return null results, validating model specificity. We further investigate structural barriers deterring non-investors, identifying loss aversion and information asymmetry as primary friction points. To deepen our behavioral insights, we expose a stark Dunning-Kruger effect among overconfident retail traders and measure the impact of "finfluencers" on high-risk asset adoption. Finally, we implement Histogram-based Gradient Boosting Classifiers to predict participation, asset choice, and investment horizons based on basic demographic and behavioral metrics. Our predictive models achieve strong discriminatory power for baseline participation (AUC=0.76) and asset allocation (AUC=0.83), validating that while market entry is structurally gated, post-entry behavior is heavily dictated by psychographic traits and financial literacy.**

***Index Terms*—Financial Inclusion, Securities Markets, Household Finance, Behavioral Economics, Predictive Modeling**

I. Introduction

The democratization of capital markets is essential for broad-based economic growth and household wealth accumulation. In emerging economies like India, retail participation in securities has witnessed a significant surge, catalyzed by digitization and the proliferation of zero-commission trading platforms. Despite this growth, participation remains highly heterogeneous.

Understanding the determinants of household participation is a central problem in financial economics. Why do certain households allocate capital to mutual funds and equities, while others restrict their savings to traditional, low-yield instruments like fixed deposits? The literature points to a combination of background risk, financial literacy, and trust in institutions. However, most existing studies rely on older data that predate the post-pandemic retail boom, the widespread adoption of digital KYC, and the systemic rise of social media financial influencers.

This paper addresses this gap by utilizing the comprehensive 2025 SEBI Household Survey. We pose four core research questions: (1) Who is likely to participate in the securities market? (2) What structural and behavioral barriers keep the majority of households out? (3) Which securities do participating households prefer, and for how long? and (4) Can we predict these outcomes given basic demographic and behavioral metrics?

The remainder of the paper is organized as follows: Section II details the dataset and methodology. Section III presents the empirical findings regarding determinants, behavioral anomalies, and securities preferences. Section IV details our predictive modeling framework. Finally, Section V concludes with highly condensed policy implications.

II. Data and Methodology

A. Dataset

We utilize micro-data from the 2025 SEBI Household Survey on Securities Market Participation, a nationally representative cross-sectional survey of $N = 109{,}430$ households administered across four geographic zones: North, South, East, and West India. Each observation corresponds to a unique household respondent, weighted for population representativeness via a pre-computed survey weight variable.

The sample is bifurcated into *active investors* (those holding at least one financial security) ($n = 27{,}882$; 25.5%) and *non-investors* ($n = 81{,}548$; 74.5%). Table I reports key demographic characteristics. The sample skews male (64.5%) and is concentrated in younger cohorts: Gen Z (18–27 years) and Millennials (28–43 years) together comprise 86.1% of respondents. Nuclear family structures predominate (84.2% of households).

The survey employs a conditional routing design. Investors were directed to dedicated sub-modules (SS_B3, SS_B10) covering information sources and investment motivations, yielding $n = 9{,}797$ complete investor sub-responses. Non-investors were routed to a separate module (SS_BB2) eliciting up to three self-reported barriers to participation, yielding $n = 14{,}794$ barrier responses. All group-level percentages for

Based on the 2025 SEBI Household Survey on Securities Market Participation.

TABLE I
SAMPLE COMPOSITION AND PARTICIPATION RATES

	N	% of Sample	Participation Rate
Gender			
Male	70,616	64.5	30.8%
Female	38,814	35.5	15.8%
Life Stage			
Gen Z (18–27)	49,035	44.8	24.3%
Millennial (28–43)	45,235	41.3	28.1%
Gen X (44–59)	12,806	11.7	22.9%
Baby Boomer (60+)	2,354	2.2	13.3%
Residence			
Urban	76,931	70.3	28.8%
Rural	32,499	29.7	17.6%
Zone			
West	34,153	31.2	27.1%
South	27,885	25.5	26.8%
North	26,439	24.2	24.1%
East	20,953	19.1	22.8%

these modules are computed against the respective routing-eligible population, not the full sample.

B. Exploratory Analysis

The raw participation patterns in Table I reveal a market sharply stratified by socioeconomic position. The gender gap is the most visually immediate: male respondents participate at 30.8% against 15.8% for female respondents. The income gradient, however, is the steepest univariate signal: participation rises from 10.7% in the lowest quintile (below INR 12,500/month) to 47.6% in the highest (above INR 35,000/month), a more than fourfold difference. Urban households (28.8%) participate at nearly double the rate of rural ones (17.6%). Notably, Millennials (28–43 years) record the *highest* participation rate of any cohort (28.1%), exceeding Gen X (22.9%) and Gen Z (24.3%), suggesting the post-2020 retail boom was disproportionately captured by this age group rather than younger entrants.

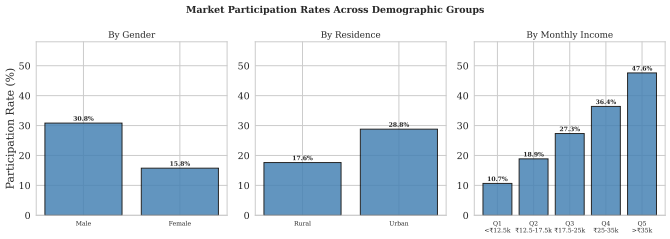

Fig. 1. Market participation rates by gender, residence, and monthly income quintile. The income gradient (10.7% to 47.6%) is the steepest univariate signal, while the gender gap (30.8% vs 15.8%) persists across all income levels.

A critical precondition for participation is product awareness. The survey's awareness module reveals a steep gradient: fixed deposits are known to 99.1% of respondents, while mutual funds and ETFs reach 67.0%, direct equity 62.0%, and derivatives just 17.9%. This awareness gap, between near-universal familiarity with traditional instruments and niche awareness of market-linked ones, maps closely onto the observed holdings distribution. Among the 27,882 active investors, MF/ETFs lead penetration (66.5%), followed by FD/RD (57.2%) and direct equity (49.3%). The co-existence of MFs and FDs as the two most-held instruments indicates that Indian retail investors are not homogenously risk-seeking; the portfolio evidence points instead to a layered allocation model where market-linked products supplement rather than replace traditional savings.

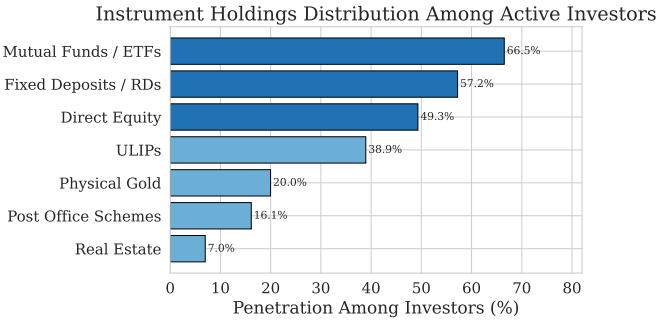

Fig. 2. Instrument holdings penetration among active investors ($n = 27{,}882$). MF/ETFs and Fixed Deposits co-dominate, indicating a layered allocation model rather than a shift away from traditional savings.

The financial literacy data deepens this picture. When presented with nine objective financial knowledge questions, investors perform unevenly: while 80%+ correctly identify that KYC can be completed online and that higher returns entail higher risk, a majority respond incorrectly or "Don't Know" to questions about compounding, diversification, and even basic SEBI tools (CAS, BSDA). This asymmetry (high procedural literacy, weak conceptual literacy) is directly relevant to the Dunning-Kruger analysis in Section III-A and to the barriers analysis, where "Lack of Knowledge" ranks as the second most-cited deterrent among non-investors.

C. Variable Operationalization

The dependent variable $Y_i \in \{0, 1\}$ indicates whether household i holds any financial security. We include eleven regressors across three groups. The *socioeconomic* block contains *Education* (continuous years of formal schooling) and *Income* (natural log of self-reported monthly household income in INR, log-transformed to address right-skew). The *demographic* block contains *Urban* (binary; urban vs. rural residence), *Gender* (binary; male = 1), and *Risk Tolerance* (ordinal; 1 = low, 2 = medium, 3 = high). The *life stage* block uses Gen Z as the reference category, with binary indicators for Millennial (28–43 years), Gen X (44–59 years), and Baby Boomer (60+ years). The *geographic* block uses the East zone as reference, with binary indicators for North, South, and West. All continuous regressors are standardized ($\mu = 0$, $\sigma = 1$) prior to estimation so that OR magnitudes are directly comparable across predictors.

D. Econometric Specification

We estimate a binary logistic regression via maximum likelihood:

$$\Pr(Y_i = 1) = \frac{1}{1 + e^{-(\beta_0 + \boldsymbol{\beta}^\top \mathbf{x}_i)}} \tag{1}$$

where $\mathbf{x}_i$ is the vector of standardized regressors. Coefficients are exponentiated to yield odds ratios (ORs), interpreted as the multiplicative change in participation odds per one-standard-deviation increase in each predictor. Statistical significance is evaluated via Wald z-tests with heteroskedasticity-consistent (HC3) standard errors; survey weights are incorporated during estimation. We note that with $N \approx 100{,}000$, statistical significance is trivially achieved for any real effect—p-values are reported for completeness but the economically meaningful metrics are OR magnitude and confidence interval width. We include 11 regressors spanning socioeconomic, demographic, and geographic dimensions; two (Gen X life stage and West zone) return ORs statistically indistinguishable from 1.0, providing a falsifiability check on the model.

E. Predictive Framework

To operationalize the regression findings, we implement Histogram-based Gradient Boosting Classifiers for three distinct prediction tasks: (Model 1) the binary likelihood of market participation; (Model 2) whether an investor holds market-linked instruments (equity or mutual funds) vs. traditional instruments only; and (Model 3) the propensity to hold equity over a long-term horizon. All models are trained on an 80/20 stratified split and evaluated via the area under the ROC curve (AUC).

III. Empirical Results

A. Determinants of Participation & Overconfidence

Table II presents the full logistic regression results ($N = 97{,}626$; McFadden pseudo-$R^2 = 0.208$, which falls in the "excellent fit" range of 0.20–0.40 on McFadden's scale and is not directly comparable to OLS R^2). Nine of eleven predictors are statistically significant; crucially, Gen X (vs. Gen Z reference) and West zone (vs. East reference) are not, with ORs of 1.015 and 1.004 respectively, providing confidence that the model is not returning spurious significance driven purely by sample size.

As depicted in Fig. 3, education and income remain the dominant drivers (OR = 1.86 and 1.80 respectively). Urban residency (1.60) and male gender (1.55) also exert substantial independent effects. The life stage results are instructive: Millennials participate *more* than Gen Z (OR = 1.14), plausibly reflecting the post-2020 retail boom activating this cohort disproportionately; Gen X is statistically indistinguishable from Gen Z; and Baby Boomers participate significantly less (OR = 0.90). On geography, the South zone underperforms East after controlling for all other variables (OR = 0.81), despite having higher raw participation rates, indicating that South's advantage in the raw tabulation is fully explained by its higher education and income levels. West is no different from East after controls.

TABLE II
Logistic Regression: Determinants of Market Participation

Predictor	OR	95% CI	z	Sig.
Socioeconomic				
Education (yrs)	1.864	[1.823, 1.907]	57.1	***
Log(Income)	1.800	[1.758, 1.843]	53.5	***

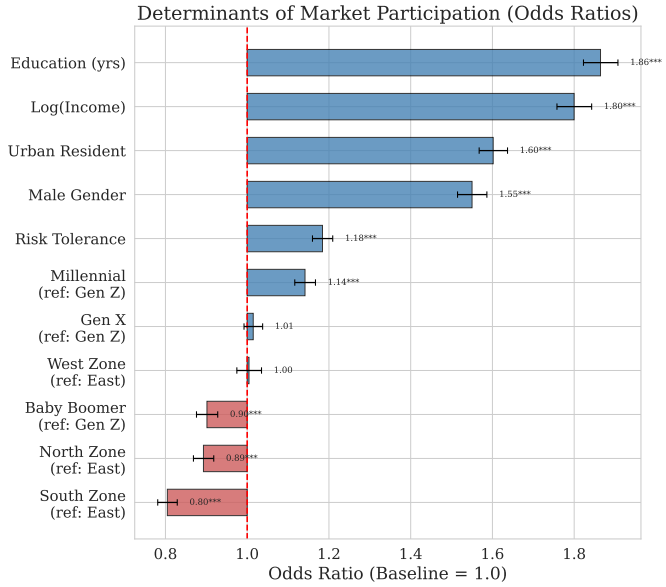

Fig. 3. Forest plot of odds ratios for determinants of market participation. Baseline is 1.0. Education and income show the highest predictive power.

For the 74.5% of households that remain completely outside the securities market, self-reported barriers (Fig. 4) indicate that behavioral frictions dominate structural ones. Specifically, "Fear of Loss" is the top barrier, closely followed by "Lack of Knowledge" and "Lack of Trust". This suggests that while digital platforms have solved access friction, the cognitive and emotional friction of investing remains high.

Diving deeper into the "Knowledge" barrier, we analyzed the divergence between self-reported market familiarity and actual scores on an objective financial literacy quiz. We discovered a profound Dunning-Kruger effect: investors who

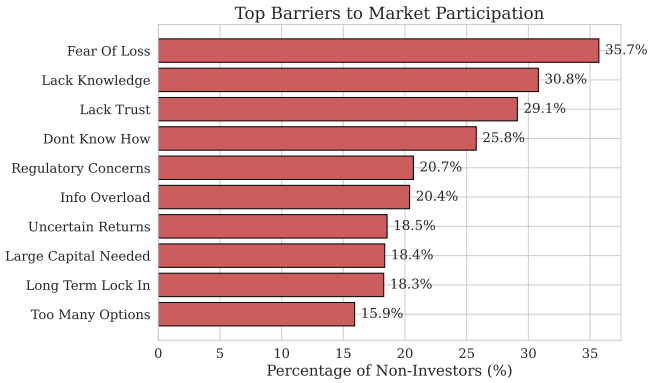

Fig. 4. Top barriers cited by non-investors. Loss aversion and information asymmetry (lack of knowledge/trust) are the primary deterrents.

are "overconfident" (high perceived familiarity, low actual knowledge) are disproportionately likely to hold high-risk assets like Futures & Options (F&O) and Cryptocurrency compared to calibrated investors (Fig. 5). This behavioral anomaly underscores why traditional models of rational participation often fail to capture modern retail dynamics.

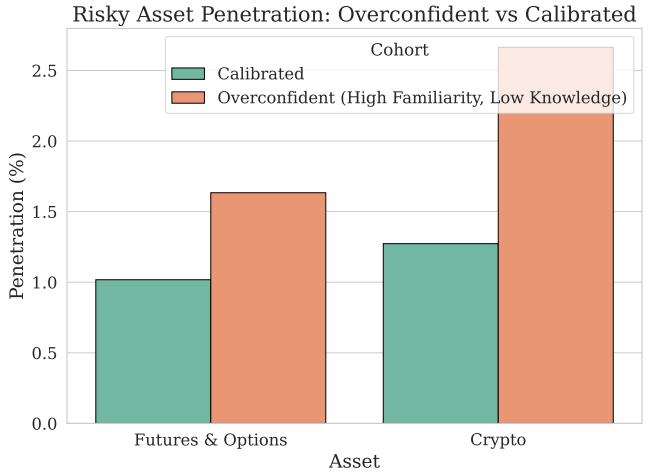

Fig. 5. Risky Asset Penetration. Overconfident investors participate in highly speculative assets at significantly higher rates than calibrated investors.

B. Securities Preferences, Demographics, and Influencers

Once households overcome the barrier to entry, their product preferences shift dynamically with income. Fig. 6 illustrates the penetration of various financial instruments across income quartiles. Fixed Deposits (FDs) remain the bedrock of Indian savings, showing uniformly high penetration. However, the adoption of market-linked securities (specifically Mutual Funds/ETFs and Direct Equity) scales dramatically in the higher income brackets, indicating that risk appetite scales non-linearly with wealth.

Crucially, the choice of securities is heavily modulated by where investors source their information. Contrasting investors who rely exclusively on Social Media "Finfluencers" against those using traditional Financial Professionals reveals a sharp behavioral divide. As seen in Fig. 7, the Finfluencer cohort is primarily motivated by "Quick Gains," whereas the professionally-advised cohort seeks "Long Term Growth." (Prevalence here is calculated as the percentage of investors within a specific information-source cohort who selected a given motive). This ties directly to the overconfidence trap discussed earlier, painting a picture of a segmented market where information source dictates risk behavior.

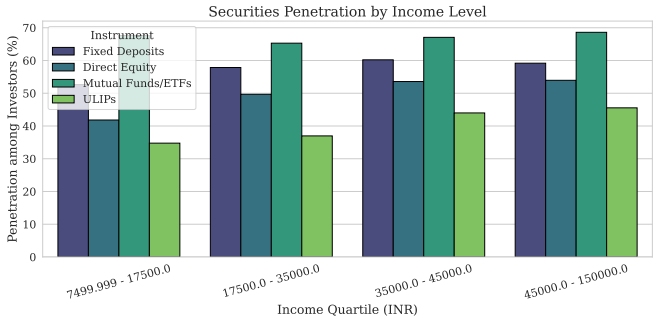

Fig. 6. Securities penetration among investors, segmented by income quartile. Market-linked instruments scale sharply with wealth.

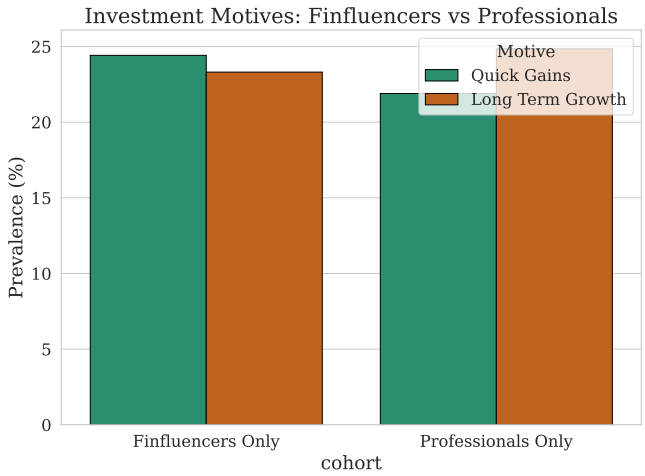

Fig. 7. Investment Motives segmented by Information Source. Prevalence denotes the percentage of investors within each cohort holding a specific motive. Social media heavily biases investors toward short-term speculative gains.

C. Investment Horizons

Holding duration preferences (Fig. 8) challenge the notion that all retail investors are short-term speculators. A significant plurality of equity and mutual fund investors define their holding periods as "Long term". In contrast, sophisticated derivative products (F&O) are predominantly utilized for "Short term" horizons, aligning with the motivations of the Finfluencer-driven cohort.

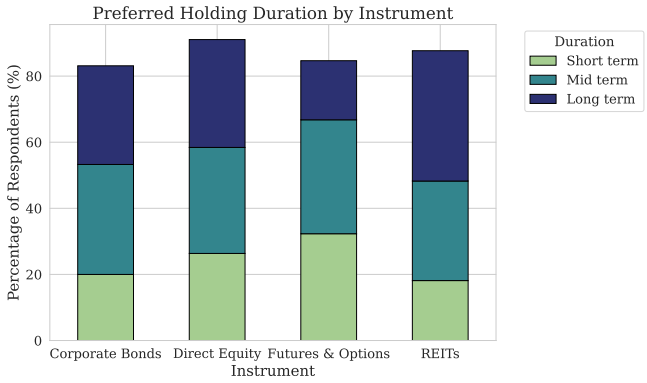

Fig. 8. Preferred holding durations across different asset classes. Direct equities are largely held for the long term, whereas derivatives skew short term.

IV. Predictive Modeling: Forecasting Household Participation

To operationalize our findings, we utilized Histogram-based Gradient Boosting Classifiers to predict household behavior. Initially, our models relied strictly on basic demographic and risk-tolerance metrics. While this was sufficient to predict baseline participation, it failed to predict post-entry behavior. To resolve this, we expanded the feature space for investor-specific models (Models 2 and 3) to include the behavioral traits uncovered in our earlier analysis.

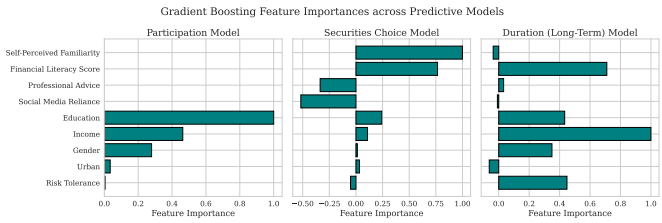

Fig. 9. Feature Importance across the three Predictive Models. Behavioral features like Familiarity and Financial Literacy heavily dominate the models predicting asset allocation and duration.

As shown in Fig. 9, injecting behavioral data drastically improves our forecasting capabilities.

A. Model 1: Predicting Participation

Objective: Predict the binary outcome of whether a household is an active investor (1) or a non-investor (0).
Data Fields Used: Years of Education, Log-transformed Monthly Income, Urban Residency (Binary), Gender (Binary), and Risk Tolerance Preference Score.
Algorithm & Split: HistGradientBoostingClassifier (200 max iterations, balanced class weights) trained on an 80/20 train-test split.
Performance: The model achieved an Area Under the Receiver Operating Characteristic Curve (AUC) of 0.76.
Insight: Basic metrics are highly effective at predicting *whether* a household will participate. Education and Income heavily dominate the decision boundary, validating that entry is structurally gated.

B. Model 2: Predicting Securities Choice

Objective: For households that *are* investors, predict if they will hold market-linked securities (Equities or Mutual Funds = 1) versus sticking exclusively to traditional instruments like Fixed Deposits (0).
Data Fields Used: All demographic features from Model 1, **plus** Self-Perceived Stock Market Familiarity, Actual Financial Literacy Score, Social Media Reliance (Binary), and Professional Advice Reliance (Binary).
Algorithm & Split: HistGradientBoostingClassifier trained on an 80/20 train-test split.
Performance: The model achieved an impressive AUC of 0.83 (up from 0.60 when using only demographics).
Insight: Predicting *how* individuals participate requires behavioral context. Once we include perceived familiarity and objective knowledge, the model's discriminatory power surges.

C. Model 3: Predicting Investment Horizon

Objective: For equity investors, predict if they will define their holding period as "Long Term" (1) versus Short/Mid-term (0).
Data Fields Used: Same extended demographic and behavioral feature set used in Model 2.
Algorithm & Split: HistGradientBoostingClassifier trained on an 80/20 train-test split.
Performance: The model achieved an AUC of 0.61 (up from 0.58).
Insight: Forecasting *how long* an investor will hold equity remains the hardest prediction task, but injecting information sources and financial literacy provides a measurable improvement over random demographic guessing.

These predictive models validate our core thesis: while structural socioeconomic factors gatekeep entry into the market, post-entry asset allocation and duration are overwhelmingly dictated by psychological factors, financial literacy, and the modern information ecosystem.

V. Conclusion and Policy Implications

The 2025 SEBI Household Survey provides compelling evidence that while the Indian securities market is growing, entry remains fundamentally gated by education and income. Once inside the market, however, traditional demographics fail to predict behavior. Instead, a dangerous cocktail of overconfidence and social media influence is driving a subset of retail investors toward highly speculative, short-term derivative trading.

For policymakers, the mandate is clear: interventions must pivot from merely reducing transaction costs to aggressively policing the quality of financial information. Bridging the knowledge gap via targeted, gamified financial literacy programs is essential. Furthermore, the undeniable Dunning-Kruger effect suggests that access to complex derivatives should perhaps be gated by objective literacy tests, rather

than self-reported familiarity, to protect the new wave of retail investors from behavioral pitfalls.
